Construction Algorithms for Higher Order Polynomial Lattice Rules

Jan Baldeaux[*], Josef Dick[†],
Julia Greslehner and Friedrich Pillichshammer[‡]

Dedicated to Gerhard Larcher on the occasion of his 50th birthday

Abstract

Higher order polynomial lattice point sets are special types of digital higher order nets which are known to achieve almost optimal convergence rates when used in a quasi-Monte Carlo algorithm to approximate high-dimensional integrals over the unit cube.

Recently it has been shown that higher order polynomial lattice point sets of "good" quality must exist. However, it was not shown how to construct such point sets avoiding an exhaustive search. This is the contribution of the present paper.

We use a component-by-component approach to construct higher order polynomial lattice rules achieving optimal convergence rates for functions of arbitrarily high smoothness and at the same time – under certain conditions on the weights – (strong) polynomial tractability. In addition, we show how to combine a sieve-type algorithm with the component-by-component approach to construct higher order polynomial lattice rules adjusting themselves to the smoothness of the

integrand up to a certain given degree. Analogous results for higher order Korobov polynomial lattice point sets are presented as well.

1 Introduction

Quasi-Monte Carlo rules are equal weight integration formulas used to approximate integrals over the unit cube $[0,1]^s$, where the dimension s is typically large. In particular, one approximates an integral $\int_{[0,1]^s} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x}$ by

$$Q_{N,s}(f) = \frac{1}{N}\sum_{n=0}^{N-1} f(\boldsymbol{x}_n) \quad \text{where } \boldsymbol{x}_0,\ldots,\boldsymbol{x}_{N-1} \in [0,1)^s.$$

Popular choices for the underlying integration nodes $\boldsymbol{x}_0,\ldots,\boldsymbol{x}_{N-1} \in [0,1)^s$ are either lattice point sets (see [14, 15]) or digital (t,m,s)-nets (see [12, 14]); in this paper, we focus on digital nets.

Recently, digital higher order nets were introduced by Dick [3] which include digital (t,m,s)-nets as special cases and have the appealing property that they can exploit the smoothness of the integrand under consideration. This is not possible with ordinary digital (t,m,s)-nets. To be more precise, if the integrand under consideration has square integrable mixed partial derivatives of order α in each variable, then digital higher order nets consisting of N points can produce integration errors converging at a rate of $N^{-\alpha+\varepsilon}$ with arbitrary small $\varepsilon > 0$.

Having established the desirable properties of digital higher order nets, an important question is how to construct them. One possible answer to this question was given in [3, Section 4.4], where it was shown how to obtain digital higher order nets from classical digital nets. The aim of the present paper is to provide constructions of digital higher order nets independent of classical digital nets. As alternative construction we consider polynomial lattice rules which first have been introduced by Niederreiter [13, 14] as special cases of digital nets and later generalized in [8] as special cases of digital higher order nets. Quasi-Monte Carlo rules using such point sets as integration nodes are nowadays known as (higher order) polynomial lattice rules. We refer to [9, 14] for more information on polynomial lattice rules. In [8] the existence of higher order polynomial lattice rules achieving optimal convergence rates was established with an averaging argument. In addition, these rules can at the same time achieve (strong) polynomial tractability. However,

this approach is purely probabilistic and gives no hint of how to construct such point sets. A further nonconstructive existence result for "good" higher order polynomial lattice rules is presented in [6]. This approach uses the concept of a figure of merit. The results presented in these papers were very encouraging. In particular, for large values of α and s, the higher order polynomial lattice rules improved on the construction based on classical digital nets from [3, Section 4.4].

In this paper we find a construction procedure producing higher order polynomial lattice rules which perform well when applied to numerical integration. In particular, we consider two cases: Firstly, we use a component-by-component (CBC) approach (an idea first used in [16]) to produce higher order polynomial lattice rules achieving the optimal rate of convergence for functions having higher order mixed partial derivatives, see Algorithm 1 and Theorem 3.1. Furthermore, by combining the CBC approach with a "sieve"-type algorithm (as used in [10]) we can even construct higher order polynomial lattice rules which automatically adjust themselves to the smoothness of the integrand in terms of the convergence of the integration error within a certain (arbitrarily high) range; see Algorithm 2 and Theorem 4.2. We point out already here, that an analogous result for lattice rules is not known.

In addition, we study a special case of higher order polynomial lattice rules, namely higher order Korobov polynomial lattice rules as introduced in [8]; see also [11] for the classical definition. We find that analogous results as for the higher order polynomial lattice rules constructed using a CBC and CBC sieve approach can be established.

The approaches to constructing digital higher order nets presented in this paper are direct, that is, we avoid employing classical digital nets, which earlier constructions (see [3, Section 4.4]) relied on. Furthermore, the higher order polynomial lattice rules are constructed to perform well when applied to numerical integration and without reference to the quality parameter t of the resulting digital higher order net.

The structure of the paper is as follows: In Section 2 we recall higher order polynomial lattice rules, discuss the function space under consideration and present a result on numerical integration in this function space employing higher order polynomial lattice rules. In Section 3 we use a CBC approach to construct higher order polynomial lattice rules achieving optimal rates of convergence for functions of a given smoothness and in Section 4 we show how to construct higher order polynomial lattice rules achieving optimal convergence rates for a given range of smoothness parameters using a CBC

sieve algorithm. Finally, in Section 5, analogous results for higher order Korobov polynomial lattice rules are established.

2 Preliminaries

In this section we introduce higher order polynomial lattice rules which can achieve arbitrarily high convergence rates, the function space under consideration, and a result on numerical integration in this function space when using higher order polynomial lattice rules.

2.1 Polynomial lattice rules for arbitrarily smooth functions

For a prime b let $\mathbb{Z}_b$ be the finite field with b elements and let $\mathbb{Z}_b((x^{-1}))$ be the field of formal Laurent series over $\mathbb{Z}_b$. Elements of $\mathbb{Z}_b((x^{-1}))$ are formal Laurent series,

$$L = \sum_{l=w}^{\infty} t_l x^{-l},$$

where w is an arbitrary integer and all $t_l \in \mathbb{Z}_b$. Note that $\mathbb{Z}_b((x^{-1}))$ contains the field of rational functions over $\mathbb{Z}_b$ as a subfield. Further let $\mathbb{Z}_b[x]$ be the set of all polynomials over $\mathbb{Z}_b$.

For an integer n let v_n be the map from $\mathbb{Z}_b((x^{-1}))$ to the interval $[0,1)$ defined by

$$v_n\left(\sum_{l=w}^{\infty} t_l x^{-l}\right) = \sum_{l=\max(1,w)}^{n} t_l b^{-l}.$$

The following definition of higher order polynomial lattice rules given in [8] is a slight generalization of the definition from [13], see also [14].

Definition 2.1 Let b be prime and let $1 \le m \le n$ be integers. For a given dimension $s \ge 1$, choose $p(x) \in \mathbb{Z}_b[x]$ with $\deg(p(x)) = n$ and let $q_1(x), \ldots, q_s(x) \in \mathbb{Z}_b[x]$. For $0 \le h < b^m$ let $h = h_0 + h_1 b + \cdots + h_{m-1} b^{m-1}$ be the b-adic expansion of h. With each such h we associate the polynomial

$$\overline{h}(x) = \sum_{r=0}^{m-1} h_r x^r \in \mathbb{Z}_b[x].$$

Then $\mathcal{S}_{p,m,n}(\boldsymbol{q})$, where $\boldsymbol{q} = (q_1(x), \ldots, q_s(x))$, is the point set consisting of the b^m points

$$\boldsymbol{x}_h = \left(v_n\left(\frac{\overline{h}(x)q_1(x)}{p(x)}\right), \ldots, v_n\left(\frac{\overline{h}(x)q_s(x)}{p(x)}\right)\right) \in [0,1)^s,$$

for $0 \le h < b^m$. A quasi-Monte Carlo rule using the point set $\mathcal{S}_{p,m,n}(\boldsymbol{q})$ is called a *polynomial lattice rule*.

Remark 2.1 Using similar arguments as for the classical case $n = m$, see [13, 14], it can be shown that the point set $S_{p,m,n}(\boldsymbol{q})$ is a digital net in the sense of [3] which can be seen as a generalisation of the classical definition of digital nets according to Niederreiter [12, 13, 14]. The generating matrices $C_1, \ldots, C_s \in \mathbb{Z}_b^{n\times m}$ of this digital net can be obtained in the following way: For $1 \le j \le s$ consider the expansions

$$\frac{q_j(x)}{p(x)} = \sum_{l=w_j}^{\infty} u_l^{(j)} x^{-l} \in \mathbb{Z}_b((x^{-1})),$$

where $w_j \in \mathbb{Z}$. Then the elements $c_{l,r}^{(j)}$ of the $n \times m$ matrix C_j over $\mathbb{Z}_b$ are given by

$$c_{l,r}^{(j)} = u_{r+l}^{(j)} \in \mathbb{Z}_b,$$

for $1 \le j \le s$, $1 \le l \le n$, $0 \le r \le m-1$.

For the rest of the paper, we make use of the following notation: We write $\vec{h}$ for vectors over $\mathbb{Z}_b$ and $\boldsymbol{h}$ for vectors over $\mathbb{Z}$ or $\mathbb{R}$. Polynomials over $\mathbb{Z}_b$ are denoted by $h(x)$ and vectors of polynomials by $\boldsymbol{h}(x)$. Furthermore, given an integer h with b-adic expansion $h = \sum_{r=0}^{\infty} h_r b^r$, we denote the associated polynomial by $\overline{h}(x)$, which is given by

$$\overline{h}(x) = \sum_{r=0}^{n-1} h_r x^r.$$

For arbitrary $\boldsymbol{k}(x) = (k_1(x), \ldots, k_s(x)) \in \mathbb{Z}_b[x]^s$ and $\boldsymbol{q}(x) = (q_1(x), \ldots, q_s(x)) \in \mathbb{Z}_b[x]^s$, we define the "inner product"

$$\boldsymbol{k}(x) \cdot \boldsymbol{q}(x) = \sum_{j=1}^{s} k_j(x) q_j(x) \in \mathbb{Z}_b[x],$$

and we write $q(x) \equiv 0 \pmod{p(x)}$ if $p(x)$ divides $q(x)$ in $\mathbb{Z}_b[x]$.

We remark here that for our results only the degree of the polynomial $p(x)$ is important and not the specific choice of $p(x)$ itself (we assume though that $p(x)$ is irreducible, but this assumption could be removed by a more complicated analysis).

2.2 Walsh functions and the function space $\mathscr{W}_{\alpha,s,\gamma}$

We now define the space of functions we are going to study. This function space is based on Walsh functions whose definition is recalled in the following.

Let $\mathbb{N}_0$ denote the set of nonnegative and $\mathbb{N}$ the set of positive integers. Each $k \in \mathbb{N}$ has a unique b-adic representation $k = \sum_{i=0}^{a} \kappa_i b^i$ with digits $\kappa_i \in \{0, \ldots, b-1\}$ for $0 \le i \le a$, where $\kappa_a \neq 0$. For $k = 0$ we have $a = 0$ and $\kappa_0 = 0$. Similarly, each $x \in [0,1)$ has a b-adic representation $x = \sum_{i=1}^{\infty} \xi_i b^{-i}$ with digits $\xi_i \in \{0, \ldots, b-1\}$ for $i \ge 1$. This representation is unique in the sense that infinitely many of the ξ_i must differ from $b-1$. We define the kth Walsh function in base b, $\mathrm{wal}_k : [0,1) \to \mathbb{C}$ by

$$\mathrm{wal}_k(x) := \exp(2\pi \mathtt{i}(\xi_1\kappa_0 + \cdots + \xi_{a+1}\kappa_a)/b).$$

For dimension $s \ge 2$ and vectors $\boldsymbol{k} = (k_1, \ldots, k_s) \in \mathbb{N}_0^s$ and $\boldsymbol{x} = (x_1, \ldots, x_s) \in [0,1)^s$ we define $\mathrm{wal}_{\boldsymbol{k}} : [0,1)^s \to \mathbb{C}$ by

$$\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}) := \prod_{j=1}^{s} \mathrm{wal}_{k_j}(x_j).$$

It follows from the definition above that Walsh functions are piecewise constant functions. For more information on Walsh functions, see, e.g., [1, 18] or [9, Appendix A].

When studying integration errors resulting from the approximation of an integral based on a digital net or digital higher order net or a (higher order) polynomial lattice rule, it is convenient to consider the Walsh series of the integrand f. In particular, for $f \in L_2([0,1]^s)$, the Walsh series of f is given by

$$f(\boldsymbol{x}) \sim \sum_{\boldsymbol{k} \in \mathbb{N}_0^s} \widehat{f}(\boldsymbol{k}) \mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}), \tag{1}$$

where the Walsh coefficients $\widehat{f}(\boldsymbol{k})$ are given by

$$\widehat{f}(\boldsymbol{k}) = \int_{[0,1]^s} f(\boldsymbol{x}) \overline{\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})} \, \mathrm{d}\boldsymbol{x}.$$

In general, the Walsh series given in equation (1) need not converge to f, however, for the space of Walsh series $\mathscr{W}_{\alpha,s,\boldsymbol{\gamma}}$, which we define in the following, it does, see also [3]. For more details on the convergence of Walsh series, we refer to [3] or [9].

Throughout the paper we assume that b is a fixed prime, all polynomials are over $\mathbb{Z}_b[x]$ and all Walsh functions are also considered in the same base b.

The function space under consideration in this paper is the space $\mathscr{W}_{\alpha,s,\boldsymbol{\gamma}} \subseteq L_2([0,1]^s)$ as introduced in [3]. Here $\boldsymbol{\gamma} = (\gamma_j)_{j=1}^{\infty}$ is a sequence of positive, nonincreasing weights, which are introduced to model the importance of different variables for our approximation problem, see [17]. For $s \in \mathbb{N}$ let $[s] := \{1, \ldots, s\}$ and for $\mathfrak{u} \subseteq [s]$ let $\gamma_{\mathfrak{u}} := \prod_{j \in \mathfrak{u}} \gamma_j$ be the weight associated with the projection onto components whose index is contained in $\mathfrak{u}$.

Given a positive integer k with base b expansion $k = \kappa_1 b^{a_1 - 1} + \kappa_2 b^{a_2 - 1} + \cdots + \kappa_v b^{a_v - 1}$, $1 \le a_v < \cdots < a_1$, $v \ge 1$, we define $\mu_\alpha(k) := a_1 + \cdots + a_{\min(v,\alpha)}$. Furthermore we put $\mu_\alpha(0) := 0$.

For $k \in \mathbb{N}_0$ and a weight $\gamma > 0$, we define a function

$$r_\alpha(\gamma, k) := \begin{cases} 1 & \text{if } k = 0, \\ \gamma b^{-\mu_\alpha(k)} & \text{otherwise.} \end{cases}$$

If we consider a vector $\boldsymbol{k} \in \mathbb{N}_0^s$ of the form $\boldsymbol{k} = (k_1, \ldots, k_s)$, we set

$$r_\alpha(\boldsymbol{\gamma}, \boldsymbol{k}) := \prod_{j=1}^{s} r_\alpha(\gamma_j, k_j).$$

Definition 2.2 The space $\mathscr{W}_{\alpha,s,\boldsymbol{\gamma}} \subseteq L_2([0,1]^s)$ consists of all Walsh series $f = \sum_{\boldsymbol{k} \in \mathbb{N}_0^s} \widehat{f}(\boldsymbol{k}) \mathrm{wal}_{\boldsymbol{k}}$ for which the norm

$$\|f\|_{\mathscr{W}_{\alpha,s,\boldsymbol{\gamma}}} := \sup_{\boldsymbol{k} \in \mathbb{N}_0^s} \frac{|\widehat{f}(\boldsymbol{k})|}{r_\alpha(\boldsymbol{\gamma}, \boldsymbol{k})}. \tag{2}$$

is finite.

For $\alpha \ge 2$, the following property was shown in [3]: Let $f : [0,1]^s \to \mathbb{R}$ be such that all mixed partial derivatives up to order α in each variable are square integrable, then $f \in \mathscr{W}_{\alpha,s,\boldsymbol{\gamma}}$. Furthermore, an inequality using a Sobolev type norm and the norm in equation (2) was shown in [3], see also [2, 4]. Consequently, the results we are going to establish in the following

for functions in $\mathscr{W}_{\alpha,s,\boldsymbol{\gamma}}$ also apply automatically to smooth functions. The assumption $\alpha > 1$ is needed to ensure that the sum of the absolute values of the Walsh coefficients converges. For the case $\alpha = 1$, which requires a different analysis, we refer to [7] or to [9].

2.3 Numerical Integration in $\mathscr{W}_{\alpha,s,\boldsymbol{\gamma}}$

We are interested in the worst-case error of multivariate integration in $\mathscr{W}_{\alpha,s,\boldsymbol{\gamma}}$ using a quasi-Monte Carlo rule $Q_{b^m,s}$, which is given by

$$e(Q_{b^m,s}, \mathscr{W}_{\alpha,s,\boldsymbol{\gamma}}) = \sup_{\substack{f \in \mathscr{W}_{\alpha,s,\boldsymbol{\gamma}} \\ \|f\|_{\mathscr{W}_{\alpha,s,\boldsymbol{\gamma}}} \le 1}} |I_s(f) - Q_{b^m,s}(f)|. \tag{3}$$

The initial error is given by

$$e(Q_{0,s}, \mathscr{W}_{\alpha,s,\boldsymbol{\gamma}}) = \sup_{\substack{f \in \mathscr{W}_{\alpha,s,\boldsymbol{\gamma}} \\ \|f\|_{\mathscr{W}_{\alpha,s,\boldsymbol{\gamma}}} \le 1}} |I_s(f)| = \|I_s\|.$$

We denote the quasi-Monte Carlo rule based on a polynomial lattice rule $S_{p,m,n}(\boldsymbol{q})$ by $Q_{b^m,s}(\boldsymbol{q})$ and the associated worst-case integration error by $e_{b^m,\alpha}(\boldsymbol{q}, p)$. The next proposition gives information on this quantity.

Proposition 2.1 *Let b be a prime and $\alpha \ge 2$ an integer. Then the worst-case integration error for multivariate integration in $\mathscr{W}_{\alpha,s,\boldsymbol{\gamma}}$ using the polynomial lattice rule $S_{p,m,n}(\boldsymbol{q})$ is given by*

$$e_{b^m,\alpha}(\boldsymbol{q}, p) = \sum_{\boldsymbol{k} \in \mathscr{D}_p(\boldsymbol{q})} r_\alpha(\boldsymbol{\gamma}, \boldsymbol{k}),$$

where

$$\begin{aligned} \mathscr{D}_p(\boldsymbol{q}) \;:=\; \big\{ \boldsymbol{k} \in \mathbb{N}_0^s \setminus \{\boldsymbol{0}\} : \overline{\boldsymbol{k}}(x) \cdot \boldsymbol{q}(x) \equiv a(x) \pmod{p(x)} \\ \text{with } \deg(a(x)) < n - m \big\}. \end{aligned} \tag{4}$$

Proof. Combine [3, equation (5.2)] with the determination of the dual net $\mathscr{D}$ of a polynomial lattice from [8, Section 4]. □

3 Component-by-component construction of polynomial lattice rules

We propose the following algorithm to construct a polynomial lattice rule that achieves higher order convergence. We remark that unlike the results presented in Section 4, we only deal with a fixed α in this section. For ease of notation, we proceed as follows: We use $q = q(x) \in \mathbb{Z}_b[x]$, $p = p(x) \in \mathbb{Z}_b[x]$ and $a = a(x) \in \mathbb{Z}_b[x]$; also, if we consider the polynomial associated with an integer k, we use $\overline{k} = \overline{k}(x) \in \mathbb{Z}_b[x]$. We put

$$G_{b,n} := \{q \in \mathbb{Z}_b[x] : \deg(q) < n\}.$$

We also make use of the following lemma, which appeared in a weaker and nonexplicit form as [8, Lemma 4.2].

Lemma 3.1 *Let $\alpha \geq 2$ be an integer. Then for every $1/\alpha < \lambda \leq 1$ we have*

$$\sum_{l=1}^{\infty} r_\alpha^\lambda(\gamma, l) \leq \gamma^\lambda C_{b,\alpha,\lambda},$$

where

$$C_{b,\alpha,\lambda} := \widetilde{C}_{b,\alpha,\lambda} + \frac{(b-1)^\alpha}{b^{\lambda\alpha} - b} \prod_{i=1}^{\alpha-1} \frac{1}{b^{\lambda i} - 1},$$

$$\widetilde{C}_{b,\alpha,\lambda} = \begin{cases} \alpha - 1 & \text{if } \lambda = 1, \\ \frac{(b-1)((b-1)^{\alpha-1} - (b^\lambda - 1)^{\alpha-1})}{(b-b^\lambda)(b^\lambda-1)^{\alpha-1}} & \text{if } \lambda < 1. \end{cases}$$

Furthermore, the series $\sum_{l=1}^{\infty} r_\alpha^\lambda(\gamma, l)$ diverges to ∞ as λ goes to $1/\alpha$ from the right.

Proof. Let $l = \lambda_1 b^{a_1 - 1} + \cdots + \lambda_v b^{a_v - 1}$ where $v \geq 1$, $0 < a_v < \cdots < a_1$ and $\lambda_i \in \{1, \ldots, b-1\}$. We divide the sum over all $l \in \mathbb{N}$ into two parts, namely firstly where $1 \leq v \leq \alpha - 1$ and secondly where $v > \alpha - 1$. For the first part we have

$$\sum_{v=1}^{\alpha-1} (b-1)^v \sum_{0 < a_v < \cdots < a_1} \frac{1}{b^{\lambda(a_1 + \cdots + a_v)}}$$

$$
\begin{aligned}
&= \sum_{v=1}^{\alpha-1}(b-1)^v \sum_{a_1=v}^{\infty} \frac{1}{b^{\lambda a_1}} \sum_{a_2=v-1}^{a_1-1} \frac{1}{b^{\lambda a_2}} \cdots \sum_{a_v=1}^{a_{v-1}-1} \frac{1}{b^{\lambda a_v}} \\
&\le \sum_{v=1}^{\alpha-1} \left(\frac{b-1}{b^\lambda-1}\right)^v = \begin{cases} \alpha-1 & \text{if } \lambda = 1, \\ \frac{(b-1)((b-1)^{\alpha-1}-(b^\lambda-1)^{\alpha-1})}{(b-b^\lambda)(b^\lambda-1)^{\alpha-1}} & \text{if } \lambda < 1, \end{cases} \\
&=: \widetilde{C}_{b,\alpha,\lambda}.
\end{aligned}
$$

For the second part we have

$$
\begin{aligned}
&(b-1)^\alpha \sum_{0<a_\alpha<\cdots<a_1} \frac{b^{a_\alpha-1}}{b^{\lambda(a_1+\cdots+a_\alpha)}} \\
&= \frac{(b-1)^\alpha}{b} \sum_{a_1=\alpha}^{\infty} \frac{1}{b^{\lambda a_1}} \sum_{a_2=\alpha-1}^{a_1-1} \frac{1}{b^{\lambda a_2}} \cdots \sum_{a_\alpha=1}^{a_{\alpha-1}-1} \frac{b^{a_\alpha}}{b^{\lambda a_\alpha}} \\
&= \frac{(b-1)^\alpha}{b} \sum_{a_\alpha=1}^{\infty} \frac{b^{a_\alpha}}{b^{\lambda a_\alpha}} \sum_{a_{\alpha-1}=a_\alpha+1}^{\infty} \frac{1}{b^{\lambda a_{\alpha-1}}} \cdots \sum_{a_2=a_3+1}^{\infty} \frac{1}{b^{\lambda a_2}} \sum_{a_1=a_2+1}^{\infty} \frac{1}{b^{\lambda a_1}} \\
&= \frac{(b-1)^\alpha}{b} \prod_{i=1}^{\alpha-1} \frac{1}{b^{\lambda i}-1} \sum_{a_\alpha=1}^{\infty} \frac{b^{a_\alpha}}{b^{\lambda a_\alpha}} \frac{1}{b^{\lambda(\alpha-1)a_\alpha}} \\
&= \frac{(b-1)^\alpha}{b^{\lambda\alpha}-b} \prod_{i=1}^{\alpha-1} \frac{1}{b^{\lambda i}-1}.
\end{aligned}
$$

Hence, we have shown that

$$
\begin{aligned}
&\gamma^\lambda \frac{(b-1)^\alpha}{b^{\lambda\alpha}-b} \prod_{i=1}^{\alpha-1} \frac{1}{b^{\lambda i}-1} \le \sum_{l=1}^{\infty} r_\alpha^\lambda(\gamma,l) \\
&\le \gamma^\lambda \left(\widetilde{C}_{b,\alpha,\lambda} + \frac{(b-1)^\alpha}{b^{\lambda\alpha}-b} \prod_{i=1}^{\alpha-1} \frac{1}{b^{\lambda i}-1} \right) =: \gamma^\lambda C_{b,\alpha,\lambda}.
\end{aligned}
$$

As $\frac{(b-1)^\alpha}{b^{\lambda\alpha}-b} \prod_{i=1}^{\alpha-1} \frac{1}{b^{\lambda i}-1} \to \infty$ whenever $\lambda \to 1/\alpha$ from the right we also obtain the second assertion. □

Now we show that a component-by-component approach can be used to construct a polynomial lattice rule that achieves higher order convergence, where for $1 \le d \le s$, we set $\boldsymbol{q}_d = (q_1, \ldots, q_d)$. Note that we consider this vector instead of $(1, q_2, \ldots, q_s)$, c.f. [5, Algorithm 4.3], as otherwise the

projection onto the first coordinate does not achieve a convergence rate of $b^{-\alpha m}$, see also [8, Remark 2.3]. The component-by-component algorithm for a fixed α is summarised in Algorithm 1.

Algorithm 1 CBC algorithm for fixed α

Require: b a prime, $s, m \in \mathbb{N}$ and weights $\boldsymbol{\gamma} = (\gamma_j)_{j\geq 1}$.

1: Choose an irreducible polynomial $p \in \mathbb{Z}_b[x]$, with $\deg(p) = n$.
2: **for** $d = 1$ to s **do**
3: find $q_d \in G_{b,n}$ by minimising $e_{b^m,\alpha}((q_1, \ldots, q_d), p)$ as a function of q_d.
4: **end for**
5: **return** $\boldsymbol{q} = (q_1, \ldots, q_s)$.

Theorem 3.1 *Let b be prime, let $s, n, m, \alpha \in \mathbb{N}$, $m \leq n$ and let $\alpha \geq 2$. Let $p \in \mathbb{Z}_b[x]$ be irreducible with $\deg(p) = n$. Suppose $(q_1^*, \ldots, q_s^*) \in G_{b,n}^s$ is constructed using Algorithm 1. Then for all $d = 1, \ldots, s$ we have:*

$$e_{b^m,\alpha}((q_1^*, \ldots, q_d^*), p) \leq \frac{1}{b^{\min(\tau m, n)}} \prod_{j=1}^{d} (1 + 3\gamma_j^{1/\tau} C_{b,\alpha,1/\tau})^\tau \quad \forall 1 \leq \tau < \alpha.$$

Proof. We firstly show the result for $d = 1$. By Proposition 2.1,

$$e_{b^m,\alpha}(q_1, p) = \sum_{k \in \mathscr{D}_p(q_1)} r_\alpha(\gamma, k).$$

The algorithm chooses q_1^* as to minimise the worst-case error, so we have

$$e_{b^m,\alpha}(q_1^*, p) \leq e_{b^m,\alpha}(q_1, p), \quad \forall q_1 \in G_{b,n}.$$

Hence for all $1/\alpha < \lambda \leq 1$ we have

$$e_{b^m,\alpha}(q_1^*, p)^\lambda \leq \frac{1}{b^n} \sum_{q_1 \in G_{b,n}} e_{b^m,\alpha}(q_1, p)^\lambda.$$

Using an argument very similar to the one used in the proof of [8, Proposition 4.3], it can be shown that for all $1/\alpha < \lambda \leq 1$

$$e_{b^m,\alpha}(q_1^*, p)^\lambda \leq \frac{1}{b^n} \sum_{q_1 \in G_{b,n}} e_{b^m,\alpha}(q_1, p)^\lambda \leq \gamma_1^\lambda C_{b,\alpha,\lambda}(b^{-m} + b^{-\lambda n}).$$

Consequently, setting $\tau = 1/\lambda$ we obtain

$$\begin{aligned} e_{b^m,\alpha}(q_1^*, p) &\leq (1 + 2\gamma_1^{\lambda} C_{b,\alpha,\lambda})^{1/\lambda} b^{-\min(m/\lambda, n)} \\ &\leq (1 + 3\gamma_1^{1/\tau} C_{b,\alpha,1/\tau})^{\tau} b^{-\min(m\tau, n)}. \end{aligned}$$

We now assume that for some $1 \leq d < s$ we have $\boldsymbol{q}_d^* \in G_{b,n}^d$ such that

$$e_{b^m,\alpha}(\boldsymbol{q}_d^*, p) \leq b^{-\min(\tau m, n)} \prod_{j=1}^{d} (1 + 3\gamma_j^{1/\tau} C_{b,\alpha,1/\tau})^{\tau}.$$

We consider

$$\begin{aligned} & e_{b^m,\alpha}((\boldsymbol{q}_d^*, q_{d+1}), p) \\ &= \sum_{(\boldsymbol{k}, k_{d+1}) \in \mathscr{D}_p(\boldsymbol{q}_d^*, q_{d+1})} r_\alpha(\boldsymbol{\gamma}, \boldsymbol{k}) r_\alpha(\gamma_{d+1}, k_{d+1}) \\ &= \sum_{\boldsymbol{k} \in \mathscr{D}_p(\boldsymbol{q}_d^*)} r_\alpha(\boldsymbol{\gamma}, \boldsymbol{k}) + \sum_{k_{d+1}=1}^{\infty} r_\alpha(\gamma_{d+1}, k_{d+1}) \sum_{\substack{\boldsymbol{k} \in \mathbb{N}_0^d \\ (\boldsymbol{k}, k_{d+1}) \in \mathscr{D}_p(\boldsymbol{q}_d^*, q_{d+1})}} r_\alpha(\boldsymbol{\gamma}, \boldsymbol{k}) \\ &= e_{b^m,\alpha}(\boldsymbol{q}_d^*, p) + \theta(\boldsymbol{q}_d^*, q_{d+1}), \end{aligned}$$

where we set

$$\theta(\boldsymbol{q}_d^*, q_{d+1}) := \sum_{k_{d+1}=1}^{\infty} r_\alpha(\gamma_{d+1}, k_{d+1}) \sum_{\substack{\boldsymbol{k} \in \mathbb{N}_0^d \\ (\boldsymbol{k}, k_{d+1}) \in \mathscr{D}_p(\boldsymbol{q}_d^*, q_{d+1})}} r_\alpha(\boldsymbol{\gamma}, \boldsymbol{k}).$$

We see from Algorithm 1 that q_{d+1}^* is chosen in such a way that the worst-case error $e_{b^m,\alpha}((\boldsymbol{q}_d^*, q_{d+1}), p)$ is minimised. Since the only dependence on q_{d+1} is in $\theta(\boldsymbol{q}_d^*, q_{d+1})$ we have $\theta(\boldsymbol{q}_d^*, q_{d+1}^*) \leq \theta(\boldsymbol{q}_d^*, q_{d+1})$ for all $q_{d+1} \in G_{b,n}$. This implies that for all $1/\alpha < \lambda \leq 1$ we have

$$\begin{aligned} \theta(\boldsymbol{q}_d^*, q_{d+1}^*)^{\lambda} &\leq \frac{1}{b^n} \sum_{q_{d+1} \in G_{b,n}} \theta(\boldsymbol{q}_d^*, q_{d+1})^{\lambda} \\ &= \frac{1}{b^n} \sum_{q_{d+1} \in G_{b,n}} \left(\sum_{k_{d+1}=1}^{\infty} r_\alpha(\gamma_{d+1}, k_{d+1}) \sum_{\substack{\boldsymbol{k} \in \mathbb{N}_0^d \\ (\boldsymbol{k}, k_{d+1}) \in \mathscr{D}_p(\boldsymbol{q}_d^*, q_{d+1})}} r_\alpha(\boldsymbol{\gamma}, \boldsymbol{k}) \right)^{\lambda} \end{aligned}$$

$$\leq \frac{1}{b^n} \sum_{q_{d+1} \in G_{b,n}} \sum_{k_{d+1}=1}^{\infty} r_\alpha^\lambda(\gamma_{d+1}, k_{d+1}) \left(\sum_{\substack{\boldsymbol{k} \in \mathbb{N}_0^d \\ (\boldsymbol{k}, k_{d+1}) \in \mathscr{D}_p(\boldsymbol{q}_d^*, q_{d+1})}} r_\alpha(\boldsymbol{\gamma}, \boldsymbol{k}) \right)^\lambda$$

$$\leq \sum_{\substack{k_{d+1}=1 \\ p | \overline{k}_{d+1}}}^{\infty} r_\alpha^\lambda(\gamma_{d+1}, k_{d+1}) \left(\sum_{\substack{\boldsymbol{k} \in \mathbb{N}_0^d \\ \overline{\boldsymbol{k}} \cdot \boldsymbol{q}_d^* \equiv a \pmod p \\ \deg(a) < n-m}} r_\alpha(\boldsymbol{\gamma}, \boldsymbol{k}) \right)^\lambda$$

$$+ \frac{1}{b^n} \sum_{\substack{k_{d+1}=1 \\ p | \overline{k}_{d+1}}}^{\infty} r_\alpha^\lambda(\gamma_{d+1}, k_{d+1}) \sum_{q_{d+1} \in G_{b,n}} \sum_{\substack{\boldsymbol{k} \in \mathbb{N}_0^d \\ \overline{\boldsymbol{k}} \cdot \boldsymbol{q}_d^* + \overline{k}_{d+1} q_{d+1} \equiv a \pmod p \\ \deg(a) < n-m}} r_\alpha^\lambda(\boldsymbol{\gamma}, \boldsymbol{k}),$$

where we used Jensen's inequality, which states that for a sequence (a_k) of nonnegative reals we have $\left(\sum a_k\right)^\lambda \leq \sum a_k^\lambda$ for any $0 < \lambda \leq 1$. Now we have

$$\sum_{\substack{k_{d+1}=1 \\ p | \overline{k}_{d+1}}}^{\infty} r_\alpha^\lambda(\gamma_{d+1}, k_{d+1}) \left(\sum_{\substack{\boldsymbol{k} \in \mathbb{N}_0^d \\ \overline{\boldsymbol{k}} \cdot \boldsymbol{q}_d^* \equiv a \pmod p \\ \deg(a) < n-m}} r_\alpha(\boldsymbol{\gamma}, \boldsymbol{k}) \right)^\lambda$$

$$\leq \frac{\gamma_{d+1}^\lambda C_{b,\alpha,\lambda}}{b^{\lambda n}} \left(1 + \sum_{\substack{\boldsymbol{k} \in \mathbb{N}_0^d \setminus \{\boldsymbol{0}\} \\ \overline{\boldsymbol{k}} \cdot \boldsymbol{q}_d^* \equiv a \pmod p \\ \deg(a) < n-m}} r_\alpha(\boldsymbol{\gamma}, \boldsymbol{k}) \right)^\lambda$$

$$\leq \frac{\gamma_{d+1}^\lambda C_{b,\alpha,\lambda}}{b^{\lambda n}} \left(1 + e_{b^m,\alpha}(\boldsymbol{q}_d^*, p)^\lambda \right),$$

where we used the following:

$$\sum_{\substack{k=1 \\ p | \overline{k}}}^{\infty} r_\alpha^\lambda(\gamma, k) = \sum_{l=1}^{\infty} r_\alpha^\lambda(\gamma, b^n l) + \sum_{l=0}^{\infty} \sum_{\substack{k=1 \\ p | \overline{k}}}^{b^n - 1} r_\alpha^\lambda(\gamma, k + b^n l).$$

For $l > 0$ we have $r_\alpha(\gamma, b^n l) \le b^{-n} r_\alpha(\gamma, l)$. Further for $1 \le k < b^n$ the polynomial p never divides $\overline{k}$ since $\deg(p) = n$. Hence

$$\sum_{\substack{k=1 \\ p|\overline{k}}}^{\infty} r_\alpha^\lambda(\gamma, k) = \sum_{l=1}^{\infty} r_\alpha^\lambda(\gamma, b^n l) \le b^{-\lambda n} \sum_{l=1}^{\infty} r_\alpha^\lambda(\gamma, l) \le \frac{\gamma^\lambda C_{b,\alpha,\lambda}}{b^{\lambda n}}.$$

Next we consider the case where $\overline{k}_{d+1}$ is not a multiple of p. Here we have

$$\begin{aligned} &\frac{1}{b^n} \sum_{q_{d+1} \in G_{b,n}} \sum_{\substack{k_{d+1}=1 \\ p\nmid \overline{k}_{d+1}}}^{\infty} r_\alpha^\lambda(\gamma_{d+1}, k_{d+1}) \left(\sum_{(\boldsymbol{k}, k_{d+1}) \in \mathcal{D}_p(\boldsymbol{q}_d^*, q_{d+1})} r_\alpha(\boldsymbol{\gamma}, \boldsymbol{k}) \right)^\lambda \\ &\le \frac{1}{b^n} \sum_{\substack{k_{d+1}=1 \\ p\nmid \overline{k}_{d+1}}}^{\infty} r_\alpha^\lambda(\gamma_{d+1}, k_{d+1}) \sum_{q_{d+1} \in G_{b,n}} \sum_{\substack{\boldsymbol{k} \in \mathbb{N}_0^d \\ \overline{\boldsymbol{k}} \cdot \boldsymbol{q}_d^* + \overline{k}_{d+1} q_{d+1} \equiv a \pmod p \\ \deg(a) < n-m}} r_\alpha^\lambda(\boldsymbol{\gamma}, \boldsymbol{k}). \end{aligned}$$

Now we have

$$\begin{aligned} &\sum_{q_{d+1} \in G_{b,n}} \sum_{\substack{\boldsymbol{k} \in \mathbb{N}_0^d \setminus \{\boldsymbol{0}\} \\ \overline{\boldsymbol{k}} \cdot \boldsymbol{q}_d^* + \overline{k}_{d+1} q_{d+1} \equiv a \pmod p \\ \deg(a) < n-m}} r_\alpha^\lambda(\boldsymbol{\gamma}, \boldsymbol{k}) \\ &= \sum_{\boldsymbol{k} \in \mathbb{N}_0^d} r_\alpha^\lambda(\boldsymbol{\gamma}, \boldsymbol{k}) \sum_{\substack{a \in \mathbb{Z}_b[x] \\ \deg(a) < n-m}} \sum_{\substack{q_{d+1} \in G_{b,n} \\ \overline{\boldsymbol{k}} \cdot \boldsymbol{q}_d^* + \overline{k}_{d+1} q_{d+1} \equiv a \pmod p}} 1 \\ &\le \sum_{\boldsymbol{k} \in \mathbb{N}_0^d} r_\alpha^\lambda(\boldsymbol{\gamma}, \boldsymbol{k}) b^{n-m} \\ &= b^{n-m} \prod_{j=1}^{d} (1 + C_{b,\alpha,\lambda} \gamma_j^\lambda). \end{aligned}$$

Hence

$$\frac{1}{b^n} \sum_{\substack{k_{d+1}=1 \\ p\nmid \overline{k}_{d+1}}}^{\infty} r_\alpha^\lambda(\gamma_{d+1}, k_{d+1}) \sum_{q_{d+1} \in G_{b,n}} \sum_{\substack{\boldsymbol{k} \in \mathbb{N}_0^d \setminus \{\boldsymbol{0}\} \\ \overline{\boldsymbol{k}} \cdot \boldsymbol{q}_d^* + \overline{k}_{d+1} q_{d+1} \equiv a \pmod p \\ \deg(a) < n-m}} r_\alpha^\lambda(\boldsymbol{\gamma}, \boldsymbol{k})$$

$$\leq \frac{1}{b^n} \sum_{k_{d+1}=1}^{\infty} r_\alpha^\lambda(\gamma_{d+1}, k_{d+1}) b^{n-m} \prod_{j=1}^{d} (1 + C_{b,\alpha,\lambda} \gamma_j^\lambda)$$

$$\leq \frac{1}{b^m} C_{b,\alpha,\lambda} \gamma_{d+1}^\lambda \prod_{j=1}^{d} (1 + C_{b,\alpha,\lambda} \gamma_j^\lambda)\,.$$

Consequently,

$$\begin{aligned}
\theta(\boldsymbol{q}_d^*, q_{d+1}^*) &\leq \left(\frac{\gamma_{d+1}^\lambda C_{b,\alpha,\lambda}}{b^{\lambda n}} (1 + e_{b^m,\alpha}(\boldsymbol{q}_d^*, p)^\lambda) \right. \\
&\quad \left. + \frac{1}{b^m} C_{b,\alpha,\lambda} \gamma_{d+1}^\lambda \prod_{j=1}^{d} (1 + C_{b,\alpha,\lambda} \gamma_j^\lambda) \right)^{1/\lambda} \\
&\leq \gamma_{d+1} C_{b,\alpha,\lambda}^{1/\lambda} \left[\frac{1}{b^{\lambda n}} + e_{b^m,\alpha}(\boldsymbol{q}_d^*, p)^\lambda + \frac{1}{b^m} \prod_{j=1}^{d} (1 + C_{b,\alpha,\lambda} \gamma_j^\lambda) \right]^{1/\lambda}.
\end{aligned}$$

We now set $\tau = 1/\lambda$ and use the induction hypothesis to obtain

$$\begin{aligned}
\theta(\boldsymbol{q}_d^*, q_{d+1}^*) &\leq \gamma_{d+1} C_{b,\alpha,1/\tau}^\tau \left(\frac{1}{b^{n/\tau}} + e_{b^m,\alpha}(\boldsymbol{q}_d^*, p)^{1/\tau} + \frac{1}{b^m} \prod_{j=1}^{d} (1 + C_{b,\alpha,1/\tau} \gamma_j^{1/\tau}) \right)^\tau \\
&\leq \gamma_{d+1} C_{b,\alpha,1/\tau}^\tau \left(\frac{3}{b^{\min(m,n/\tau)}} \prod_{j=1}^{d} (1 + 3\gamma_j^{1/\tau} C_{b,\alpha,1/\tau}) \right)^\tau \\
&= \frac{3^\tau}{b^{\min(\tau m,n)}} \gamma_{d+1} C_{b,\alpha,1/\tau}^\tau \prod_{j=1}^{d} (1 + 3\gamma_j^{1/\tau} C_{b,\alpha,1/\tau})^\tau.
\end{aligned}$$

Finally, we have

$$\begin{aligned}
e_{b^m,\alpha}(\boldsymbol{q}_{d+1}^*, p) &= e_{b^m,\alpha}(\boldsymbol{q}_d^*, p) + \theta(\boldsymbol{q}_d^*, q_{d+1}^*) \\
&\leq \frac{1}{b^{\min(\tau m,n)}} \prod_{j=1}^{d} (1 + 3\gamma_j^{1/\tau} C_{b,\alpha,1/\tau})^\tau \\
&\quad + \frac{3^\tau}{b^{\min(\tau m,n)}} \gamma_{d+1} C_{b,\alpha,1/\tau}^\tau \prod_{j=1}^{d} (1 + 3\gamma_j^{1/\tau} C_{b,\alpha,1/\tau})^\tau \\
&= \frac{1}{b^{\min(\tau m,n)}} (1 + 3^\tau \gamma_{d+1} C_{b,\alpha,1/\tau}^\tau) \prod_{j=1}^{d} (1 + 3\gamma_j^{1/\tau} C_{b,\alpha,1/\tau})^\tau
\end{aligned}$$

$$\leq \quad \frac{1}{b^{\min(\tau m,n)}} \prod_{j=1}^{d+1} (1+3\gamma_j^{1/\tau} C_{b,\alpha,1/\tau})^{\tau},$$

where we again used Jensen's inequality. □

From Theorem 3.1 we obtain the following corollary.

Corollary 3.1 *Let b be prime, let $s, n, m, \alpha \in \mathbb{N}$, $m \leq n$ and $\alpha \geq 2$. Let $p \in \mathbb{Z}_b[x]$ be irreducible with $\deg(p) = n$ and suppose $\boldsymbol{q}^* \in G_{b,n}^s$ is constructed using Algorithm 1.*

- *We have*

$$e_{b^m,\alpha}(\boldsymbol{q}^*, p) \leq \frac{c_{s,\alpha,\boldsymbol{\gamma},\delta}}{b^{\min((\alpha-\delta)m,n)}} \quad \forall 0 < \delta \leq \alpha - 1,$$

  where

$$c_{s,\alpha,\boldsymbol{\gamma},\delta} := \prod_{j=1}^{s} \left(1 + 3\gamma_j^{\frac{1}{\alpha-\delta}} C_{b,\alpha,\frac{1}{\alpha-\delta}}\right)^{\alpha-\delta}.$$

- *Suppose $\sum_{j=1}^{\infty} \gamma_j^{\frac{1}{\alpha-\delta}} < \infty$, then $c_{s,\alpha,\boldsymbol{\gamma},\delta} \leq c_{\infty,\alpha,\boldsymbol{\gamma},\delta} < \infty$ and we have*

$$e_{b^m,\alpha}(\boldsymbol{q}^*, p) \leq \frac{c_{\infty,\alpha,\boldsymbol{\gamma},\delta}}{b^{\min((\alpha-\delta)m,n)}} \quad \forall 0 < \delta \leq \alpha - 1.$$

  Thus the worst-case error is bounded independently of the dimension.

- *Under the assumption $A := \limsup_{s\to\infty} \sum_{j=1}^{s} \gamma_j/(\log s) < \infty$ we obtain $c_{s,\alpha,\boldsymbol{\gamma},(\alpha-1)} \leq \widetilde{c}_\eta s^{2C_{b,\alpha,1}(A+\eta)}$ and therefore*

$$e_{b^m,\alpha}(\boldsymbol{q}^*, p) \leq \frac{\widetilde{c}_\eta s^{2C_{b,\alpha,1}(A+\eta)}}{b^m} \quad \forall \eta > 0,$$

  where $\widetilde{c}_\eta$ depends only on η. Thus the worst-case error satisfies a bound which depends only polynomially on the dimension.

Proof. The first part follows from Theorem 3.1 by setting $\tau = \alpha - \delta$. The second and the third part follow from the first part in exactly the same way as in the proof of [5, Corollary 4.5]. □

The above result shows that higher order polynomial lattice rules can achieve a worst-case error satisfying at the same time the almost optimal convergence rate and a bound which depends only polynomially (or even does not depend) on the dimension s (the technical term for such a behavior is (strong) polynomial tractability). Until now it is not known whether this is possible for ordinary lattice rules.

4 Optimal convergence rates for a range of smoothness parameters

In this section, we construct polynomial lattices which are optimal for a range of smoothness parameters; we use α and τ_α to denote the smoothness, where $2 \le \alpha \le \beta$, $1 \le \tau_\alpha < \alpha$.

We set

$$A_{m,n,s,\alpha,p}(\lambda) := \frac{1}{b^{sn}} \sum_{\boldsymbol{q}_s \in G_{b,n}^s} e^{\lambda}_{b^m,\alpha}(\boldsymbol{q}_s, p).$$

Proposition 4.1 *For $\alpha \ge 2$ and $1/\alpha < \lambda \le 1$ we have*

$$A_{m,n,s,\alpha,p}(\lambda) \le \frac{2}{b^{\min(m,\lambda n)}} \left(-1 + \prod_{j=1}^{s} (1 + \gamma_j^{\lambda} C_{b,\alpha,\lambda}) \right).$$

Proof. Using Proposition 2.1 and Jensen's inequality we obtain,

$$\begin{aligned} A_{m,n,s,\alpha,p}(\lambda) &\le \frac{1}{b^{sn}} \sum_{\boldsymbol{q} \in G_{b,n}^s} \sum_{\boldsymbol{k} \in \mathscr{D}_p(\boldsymbol{q})} r_\alpha^{\lambda}(\boldsymbol{\gamma}, \boldsymbol{k}) \\ &= \sum_{\boldsymbol{k} \in \mathbb{N}_0^s \setminus \{\boldsymbol{0}\}} r_\alpha^{\lambda}(\boldsymbol{\gamma}, \boldsymbol{k}) \frac{1}{b^{sn}} \sum_{\substack{\boldsymbol{q} \in G_{b,n}^s \\ \overline{\boldsymbol{k}} \cdot \boldsymbol{q} \equiv a \pmod p \\ \deg(a) < n-m}} 1. \end{aligned} \tag{5}$$

In the case where all components of $\overline{\boldsymbol{k}}$ are multiples of p every $\boldsymbol{q}$ satisfies the equation $\overline{\boldsymbol{k}} \cdot \boldsymbol{q} \equiv 0 \pmod p$ and hence we have

$$\frac{1}{b^{sn}} \sum_{\substack{\boldsymbol{q} \in G_{b,n}^s \\ \overline{\boldsymbol{k}} \cdot \boldsymbol{q} \equiv a \pmod p \\ \deg(a) < n-m}} 1 = 1$$

and the sum over all $\overline{\boldsymbol{k}}$ which satisfy this condition is therefore bounded by

$$\sum_{\substack{\boldsymbol{k} \in \mathbb{N}_0^s \setminus \{\boldsymbol{0}\} \\ \overline{\boldsymbol{k}} \equiv \boldsymbol{0} \pmod p}} r_\alpha^{\lambda}(\boldsymbol{\gamma}, \boldsymbol{k}) = -1 + \prod_{j=1}^{s} \sum_{\substack{k=0 \\ p \mid \overline{k}}}^{\infty} r_\alpha^{\lambda}(\gamma_j, k).$$

Now we have

$$\sum_{\substack{k=0\\ p|\overline{k}}}^{\infty} r_\alpha^\lambda(\gamma_j,k) = \sum_{l=0}^{\infty} r_\alpha^\lambda(\gamma_j,b^n l) + \sum_{l=0}^{\infty}\sum_{\substack{k=1\\ p|\overline{k}}}^{b^n-1} r_\alpha^\lambda(\gamma_j,k+b^n l).$$

For $l>0$ we have $r_\alpha(\gamma_j,b^n l)\le b^{-n} r_\alpha(\gamma_j,l)$ and further for $1\le k<b^n$ the polynomial p never divides $\overline{k}$ since $\deg(p)=n$. Hence

$$\sum_{\substack{k=0\\ p|\overline{k}}}^{\infty} r_\alpha^\lambda(\gamma_j,k) = 1+\sum_{l=1}^{\infty} r_\alpha^\lambda(\gamma_j,b^n l) \le 1+\frac{1}{b^{\lambda n}}\sum_{l=1}^{\infty} r_\alpha^\lambda(\gamma_j,l)\,.$$

Therefore,

$$\begin{aligned}\sum_{\substack{\boldsymbol{k}\in\mathbb{N}_0^s\setminus\{\boldsymbol{0}\}\\ \overline{\boldsymbol{k}}\equiv\boldsymbol{0} \pmod p}} r_\alpha^\lambda(\boldsymbol{\gamma},\boldsymbol{k}) &\le -1+\prod_{j=1}^{s}(1+b^{-\lambda n}\gamma_j^\lambda C_{b,\alpha,\lambda})\\ &= \sum_{\emptyset\ne\mathfrak{u}\subseteq[s]} b^{-|\mathfrak{u}|\lambda n}\gamma_{\mathfrak{u}}^\lambda C_{b,\alpha,\lambda}^{|\mathfrak{u}|}\\ &\le \frac{1}{b^{\lambda n}}\left(-1+\prod_{j=1}^{s}(1+\gamma_j^\lambda C_{b,\alpha,\lambda})\right).\end{aligned}$$

In the case where there is at least one component of $\overline{\boldsymbol{k}}$ which is not a multiple of p we have

$$\frac{1}{b^{sn}}\sum_{\substack{\boldsymbol{q}\in G_{b,n}^s\\ \overline{\boldsymbol{k}}\cdot\boldsymbol{q}\equiv a \pmod p\\ \deg(a)<n-m}} 1 = \frac{1}{b^m}$$

and therefore this part of equation (5) is bounded by

$$\begin{aligned}\frac{1}{b^m}\sum_{\substack{\boldsymbol{k}\in\mathbb{N}_0^s\setminus\{\boldsymbol{0}\}\\ \overline{\boldsymbol{k}}\not\equiv\boldsymbol{0} \pmod p}} r_\alpha^\lambda(\boldsymbol{\gamma},\boldsymbol{k}) &\le \frac{1}{b^m}\sum_{\boldsymbol{k}\in\mathbb{N}_0^s\setminus\{\boldsymbol{0}\}} r_\alpha^\lambda(\boldsymbol{\gamma},\boldsymbol{k})\\ &\le \frac{1}{b^m}\left(-1+\prod_{j=1}^{s}(1+\gamma_j^\lambda C_{b,\alpha,\lambda})\right).\end{aligned}$$

Altogether we now obtain that

$$\begin{aligned} A_{m,n,s,\alpha,p}(\lambda) &\leq \left(\frac{1}{b^m}+\frac{1}{b^{\lambda n}}\right)\left(-1+\prod_{j=1}^{s}(1+\gamma_j^{\lambda}C_{b,\alpha,\lambda})\right) \\ &\leq \frac{2}{b^{\min(m,\lambda n)}}\left(-1+\prod_{j=1}^{s}(1+\gamma_j^{\lambda}C_{b,\alpha,\lambda})\right) \end{aligned}$$

as required. □

Let $\alpha \leq \beta$ and set $n = \beta m$. Let ν denote the equiprobable measure on $G^s_{b,\beta m}$. For $c \geq 1$ and $1 \leq \tau < \alpha \leq \beta$ the following set is introduced:

$$\mathscr{C}_{b,\alpha}(c,\tau) := \left\{\boldsymbol{q} \in G^s_{b,\beta m} : e_{b^m,\alpha}(\boldsymbol{q},p) \leq E_{b,\alpha,\boldsymbol{\gamma},s,m}(c,\tau)\right\}, \tag{6}$$

where

$$E_{b,\alpha,\boldsymbol{\gamma},s,m}(c,\tau) := \frac{2^\tau c^\tau}{b^{\tau m}}\left(-1+\prod_{j=1}^{s}(1+\gamma_j^{1/\tau}C_{b,\alpha,1/\tau})\right)^{\tau}.$$

Furthermore, let

$$\begin{aligned} \mathscr{C}_{b,\alpha}(c) &:= \bigcap_{1\leq\tau<\alpha}\mathscr{C}_{b,\alpha}(c,\tau) \\ &= \left\{\boldsymbol{q} \in G^s_{b,\beta m} : e_{b^m,\alpha}(\boldsymbol{q},p) \leq E_{b,\alpha,\boldsymbol{\gamma},s,m}(c,\tau)\ \forall 1 \leq \tau < \alpha\right\}. \end{aligned} \tag{7}$$

(Note that the intersection $\bigcap_{1\leq\tau<\alpha}\mathscr{C}_{b,\alpha}(c,\tau)$ can be understood as an intersection of finitely many sets since $\mathscr{C}_{b,\alpha}(c,\tau)$ has only finitely many elements.)

Lemma 4.1 *Let $c \geq 1$ and $1 \leq \tau < \alpha \leq \beta$, then we have*

$$\nu(\mathscr{C}_{b,\alpha}(c,\tau)) > 1 - c^{-1}.$$

Proof. We denote $\overline{\mathscr{C}}_{b,\alpha}(c,\tau) := G^s_{b,\beta m} \setminus \mathscr{C}_{b,\alpha}(c,\tau)$. Then for all $1 \leq \tau < \alpha$ we have

$$\begin{aligned} A_{m,\beta m,s,\alpha,p}(1/\tau) &= \frac{1}{b^{s\beta m}}\sum_{\boldsymbol{q}\in G^s_{b,\beta m}} e^{1/\tau}_{b^m,\alpha}(\boldsymbol{q},p) \\ &> \nu(\overline{\mathscr{C}}_{b,\alpha}(c,\tau))\frac{2c}{b^m}\left(-1+\prod_{j=1}^{s}(1+\gamma_j^{1/\tau}C_{b,\alpha,1/\tau})\right). \end{aligned}$$

Now using Proposition 4.1 we obtain $\nu(\overline{\mathscr{C}}_{b,\alpha}(c,\tau)) < c^{-1}$ and the result follows. □

Lemma 4.2 *Let $c \geq 1$, then we have*

$$\nu(\mathscr{C}_{b,\alpha}(c)) > 1 - c^{-1}.$$

Proof. Let $1 \leq \tau_* < \alpha$ be such that

$$E_{b,\alpha,\boldsymbol{\gamma},s,m}(c,\tau_*) = \inf_{1\leq\tau<\alpha} E_{b,\alpha,\boldsymbol{\gamma},s,m}(c,\tau)$$

(note that by Lemma 3.1 we have $E_{b,\alpha,\boldsymbol{\gamma},s,m}(c,\tau) \to \infty$ whenever $\tau \to \alpha^-$ and hence we can find τ_* with the demanded property). Then we have

$$\mathscr{C}_{b,\alpha}(c,\tau_*) \subseteq \bigcap_{1\leq\tau<\alpha} \mathscr{C}_{b,\alpha}(c,\tau) = \mathscr{C}_{b,\alpha}(c)$$

and hence the result follows from Lemma 4.1. □

If we choose $c = \beta$ in Lemma 4.2, then we obtain $\nu(\mathscr{C}_{b,\alpha}(\beta)) > 1 - \beta^{-1}$ and consequently we have

$$\nu\left(\bigcap_{\alpha=2}^{\beta} \mathscr{C}_{b,\alpha}(\beta)\right) = 1 - \nu\left(\bigcup_{\alpha=2}^{\beta} \overline{\mathscr{C}}_{b,\alpha}(\beta)\right) \geq 1 - \sum_{\alpha=2}^{\beta} \nu(\overline{\mathscr{C}}_{b,\alpha}(\beta)) > 0.$$

Hence we obtain the following theorem which establishes the existence of a $\boldsymbol{q}^* \in G^s_{b,\beta m}$ which achieves the optimal convergence rate for a range of α's.

Theorem 4.1 *Let $\beta, m, s \in \mathbb{N}$, $\beta \geq 2$ and let $p \in \mathbb{Z}_b[x]$ with $\deg(p) = \beta m$. Then there exists a $\boldsymbol{q}^* \in G^s_{b,\beta m}$ such that*

$$e_{b^m,\alpha}(\boldsymbol{q}^*, p) \leq \frac{2^{\tau_\alpha}\beta^{\tau_\alpha}}{b^{\tau_\alpha m}} \left(-1 + \prod_{j=1}^{s}(1 + \gamma_j^{1/\tau_\alpha} C_{b,\alpha,1/\tau_\alpha})\right)^{\tau_\alpha} \tag{8}$$

for all $2 \leq \alpha \leq \beta$ and for all $1 \leq \tau_\alpha < \alpha$.

The proof of Theorem 4.1 suggests that in principle we can find $\boldsymbol{q}^*$ which satisfies equation (8) for all $2 \leq \alpha \leq \beta$ and all $1 \leq \tau_\alpha < \alpha$ by using a so-called "sieve algorithm" which will be explained in the following.

Use a computer search to find $\lfloor (1 - \beta^{-1}) b^{\beta m s} \rfloor + 1$ of the $b^{\beta m s}$ vectors $\boldsymbol{q}$ in $G^s_{b,\beta m}$ which satisfy

$$e_{b^m,2}(\boldsymbol{q}, p) \leq E_{b,2,\boldsymbol{\gamma},s,m}(\beta, \tau_2) \quad \forall 1 \leq \tau_2 < 2,$$

and label this set $\mathscr{T}_2$. By Lemma 4.2 we know that at least such a number of vectors exists.

Then proceed by using a computer search to find $\lfloor (1-2\beta^{-1})b^{\beta ms}\rfloor + 1$ vectors $\boldsymbol{q}$ in $\mathscr{T}_2$ which satisfy

$$e_{b^m,3}(\boldsymbol{q},p) \le E_{b,3,\boldsymbol{\gamma},s,m}(\beta,\tau_3) \quad \forall 1 \le \tau_3 < 3$$

and label this set $\mathscr{T}_3$. Since

$$\nu\left(\bigcap_{\alpha=2}^{3} \mathscr{C}_{b,\alpha}(\beta)\right) \;=\; 1-\nu\left(\bigcup_{\alpha=2}^{3} \overline{\mathscr{C}}_{b,\alpha}(\beta)\right) \ge 1-\sum_{\alpha=2}^{3}\nu(\overline{\mathscr{C}}_{b,\alpha}(\beta)) > 1-\frac{2}{\beta},$$

we know that there are at least $\lfloor (1-2\beta^{-1})b^{\beta ms}\rfloor + 1$ values in $\mathscr{T}_2$ to populate the set $\mathscr{T}_3$.

In the same way we proceed to construct the sets $\mathscr{T}_4,\ldots,\mathscr{T}_\beta$. Theorem 4.1 guarantees that $\mathscr{T}_\beta$ is not empty and we may select $\boldsymbol{q}^*$ to be any vector from $\mathscr{T}_\beta$. This vector satisfies equation (8) for all $2 \le \alpha \le \beta$ and all $1 \le \tau_\alpha < \alpha$.

However, in practice such a search algorithm would not be applicable since it is much too time consuming. For this reason we show in the following how the sieve algorithm may be combined with the component-by-component (CBC) algorithm which makes the search algorithm applicable. Such an algorithm, we call it "CBC sieve algorithm", is presented in Algorithm 2. For its statement we use the following notation:

For $2 \le \alpha \le \beta$ and $p \in \mathbb{Z}_b[x]$ with $\deg(p) = \beta m$ we define the following: for $d = 0$ and $q_1 \in G_{b,\beta m}$ we set

$$\theta_\alpha(0,q_1) := e_{b^m,\alpha}(q_1,p),$$

and for $d \in \mathbb{N}$, $\boldsymbol{q}_d \in G_{b,\beta m}^d$ and $q_{d+1} \in G_{b,\beta m}$ we set

$$\theta_\alpha(\boldsymbol{q}_d,q_{d+1}) := e_{b^m,\alpha}((\boldsymbol{q}_d,q_{d+1}),p) - e_{b^m,\alpha}(\boldsymbol{q}_d,p).$$

Furthermore, for short we use the notation

$$M_{d,\alpha,\boldsymbol{\gamma}}(\tau) := \frac{1}{b^m}\prod_{j=1}^{d}(1+3\beta\gamma_j^{1/\tau}C_{b,\alpha,1/\tau}).$$

Now we prove the following result.

Algorithm 2 CBC sieve algorithm for $2 \leq \alpha \leq \beta$

Require: b a prime, $s, m, \beta \in \mathbb{N}$, $\beta \geq 2$, and $p \in \mathbb{Z}_b[x]$ with $\deg(p) = \beta m$.

1: Set $\mathscr{T}_{1,d} := G_{b,\beta m}$ for all $1 \leq d \leq s$ and $\boldsymbol{q}_0^* = 0$.
2: **for** $d = 0$ to $s-1$ **do**
3: **for** $\alpha = 2$ to β **do**
4: perform a computer search to find $\lfloor (1-(\alpha-1)\beta^{-1})b^{\beta m} \rfloor + 1$ elements q in $\mathscr{T}_{\alpha-1,d+1}$ to populate the set $\mathscr{T}_{\alpha,d+1}$, which is a subset of
5: **if** $d = 0$ **then**
6:

$$\left\{ q \in \mathscr{T}_{\alpha-1,d+1} : \theta_\alpha(0,q) \leq \frac{1}{b^{\tau_\alpha m}} \left(1 + 3\gamma_1^{1/\tau_\alpha} C_{b,\alpha,1/\tau_\alpha}\right)^{\tau_\alpha} \ \forall 1 \leq \tau_\alpha < \alpha \right\}$$

7: **else**
8:

$$\left\{ q \in \mathscr{T}_{\alpha-1,d+1} : \theta_\alpha(\boldsymbol{q}_d^*,q) \leq \left(3\beta\gamma_{d+1}^{1/\tau_\alpha} C_{b,\alpha,1/\tau_\alpha} M_{d,\alpha,\boldsymbol{\gamma}}(\tau_\alpha)\right)^{\tau_\alpha} \ \forall 1 \leq \tau_\alpha < \alpha \right\}$$

9: **end if**
10: **end for**
11: Select $q_{d+1}^* \in \mathscr{T}_{\beta,d+1}$.
12: Set $\boldsymbol{q}_{d+1}^* = (\boldsymbol{q}_d^*, q_{d+1}^*)$.
13: **end for**
14: **return** $\boldsymbol{q}^* = \boldsymbol{q}_s^*$.

Theorem 4.2 *Let $s, m, \beta \in \mathbb{N}$, $\beta \geq 2$, then Algorithm 2 constructs a vector $\boldsymbol{q}_d^* \in G_{b,\beta m}^d$ such that*

$$e_{b^m,\alpha}(\boldsymbol{q}_d^*, p) \leq \frac{1}{b^{\tau_\alpha m}} \prod_{j=1}^{d} (1 + 3\beta\gamma_j^{1/\tau_\alpha} C_{b,\alpha,1/\tau_\alpha})^{\tau_\alpha}$$

for all $1 \leq \tau_\alpha < \alpha$ and for all $2 \leq \alpha \leq \beta$.

To prove Theorem 4.2 we introduce the following set: for $\boldsymbol{q}_d \in G_{b,\beta m}^d$ let $\mathscr{F}_{b,\alpha}(c, \boldsymbol{q}_d)$ be the set of all $q_{d+1} \in G_{b,\beta m}$ such that

$$\theta_\alpha(\boldsymbol{q}_d, q_{d+1}) \leq \left(3c\gamma_{d+1}^{1/\tau_\alpha} C_{b,\alpha,1/\tau_\alpha} M_{d,\alpha,\boldsymbol{\gamma}}(\tau_\alpha)\right)^{\tau_\alpha} \tag{9}$$

for all $1 \leq \tau_\alpha < \alpha$.

Lemma 4.3 *Let $2 \leq \alpha \leq \beta$ and let $c \geq 1$. Assume that there exists a $\boldsymbol{q}_d \in G^d_{b,\beta m}$ such that*

$$e_{b^m,\alpha}(\boldsymbol{q}_d, p) \leq M_{d,\alpha,\boldsymbol{\gamma}}(\tau_\alpha)^{\tau_\alpha} \tag{10}$$

for all $1 \leq \tau_\alpha < \alpha$ and for all $2 \leq \alpha \leq \beta$. Then

$$\nu\left(\mathscr{F}_{b,\alpha}(c, \boldsymbol{q}_d)\right) > 1 - c^{-1}.$$

Proof. From the proof of Theorem 3.1 and using assumption (10) for all $1/\alpha < \lambda \leq 1$ we have

$$\begin{aligned}
&\frac{1}{b^{\beta m}} \sum_{q_{d+1} \in G_{b,\beta m}} \theta_\alpha(\boldsymbol{q}^*_d, q_{d+1})^\lambda \\
&\leq \gamma^\lambda_{d+1} C_{b,\alpha,\lambda} \left(\frac{1}{b^{\lambda\alpha m}} + e_{b^m,\alpha}(\boldsymbol{q}^*_d, p)^\lambda + \frac{1}{b^m} \prod_{j=1}^{d} (1 + \gamma^\lambda_j C_{b,\alpha,\lambda}) \right) \\
&\leq 3\gamma^\lambda_{d+1} C_{b,\alpha,\lambda} M_{d,\alpha,\boldsymbol{\gamma}}(1/\lambda).
\end{aligned}$$

From this the result follows in the same way as in the proof of Lemmas 4.1 and 4.2. □

Now we give the proof of Theorem 4.2.

Proof. We proceed by induction on d and firstly show the result for $d = 1$. Having fixed $d = 1$, we proceed by induction on α. For $q \in \mathscr{C}_{b,\alpha}(\beta)$ we have (see equation (7))

$$e_{b^m,\alpha}(q, p) \leq \frac{1}{b^{\tau_\alpha m}} (1 + 3\beta\gamma_1^{1/\tau_\alpha} C_{b,\alpha,1/\tau_\alpha})^{\tau_\alpha} \quad \forall 1 \leq \tau_\alpha < \alpha\,,$$

for $2 \leq \alpha \leq \beta$. According to Lemma 4.2, $\nu(\mathscr{C}_{b,\alpha}(\beta)) > 1 - \beta^{-1}$, $2 \leq \alpha \leq \beta$, hence there are $\lfloor (1 - \beta^{-1}) b^{\beta m} \rfloor + 1$ elements to populate $\mathscr{T}_{2,1}$. Assume now that for $2 \leq \alpha < \beta$, there are $\lfloor (1 - (\alpha - 1)\beta^{-1}) b^{\beta m} \rfloor + 1$ elements to populate $\mathscr{T}_{\alpha,1}$, hence $\nu(\mathscr{T}_{\alpha,1}) > 1 - (\alpha - 1)\beta^{-1}$. We want to show that

$$\begin{aligned}
&\nu\left(\{q \in \mathscr{T}_{\alpha,1} : e_{b^m,\alpha+1}(q, p) \leq M_{1,\alpha+1,\boldsymbol{\gamma}}(\tau_{\alpha+1})^{\tau_{\alpha+1}} \, \forall 1 \leq \tau_{\alpha+1} < \alpha + 1\}\right) \\
&> 1 - \alpha\beta^{-1},
\end{aligned} \tag{11}$$

which implies that there are $\lfloor(1-\alpha\beta^{-1})b^{\beta m}\rfloor+1$ elements to populate $\mathscr{T}_{\alpha+1,1}$. But

$$\begin{aligned}&\{q \in \mathscr{T}_{\alpha,1} : e_{b^m,\alpha+1}(q,p) \leq M_{1,\alpha+1,\boldsymbol{\gamma}}(\tau_{\alpha+1})^{\tau_{\alpha+1}}\, \forall 1 \leq \tau_{\alpha+1} < \alpha+1\}\\ &= \mathscr{T}_{\alpha,1} \cap \{q \in G_{b,\beta m} : e_{b^m,\alpha+1}(q,p) \leq M_{1,\alpha+1,\boldsymbol{\gamma}}(\tau_{\alpha+1})^{\tau_{\alpha+1}} \forall 1 \leq \tau_{\alpha+1} < \alpha+1\}\,,\end{aligned}$$

hence we get equation (11) from the induction assumption and from Lemma 4.2. Thus we have proven the assertion for $d = 1$.

We now assume that for $1 \leq d < s$, the algorithm has found $\boldsymbol{q}_d^*$ so that

$$e_{b^m,\alpha}(\boldsymbol{q}_d^*, p) \leq M_{d,\alpha,\boldsymbol{\gamma}}(\tau_\alpha)^{\tau_\alpha} \tag{12}$$

for all $1 \leq \tau_\alpha < \alpha$ and for all $2 \leq \alpha \leq \beta$ and again we proceed by induction. According to Lemma 4.3, under the assumption (12), we have

$$\nu\left(\mathscr{F}_{b,\alpha}(\beta, \boldsymbol{q}_d^*)\right) > 1 - \beta^{-1} \quad \forall 2 \leq \alpha \leq \beta,$$

hence there are $\lfloor(1-\beta^{-1})b^{\beta m}\rfloor + 1$ elements to populate $\mathscr{T}_{2,d+1}$. We now assume that for $2 \leq \alpha < \beta$, there are $\lfloor(1-(\alpha-1)\beta^{-1})b^{\beta m}\rfloor + 1$ elements to populate $\mathscr{T}_{\alpha,d+1}$, hence $\nu(\mathscr{T}_{\alpha,d+1}) > (1-(\alpha-1)\beta^{-1})$.

Since

$$\begin{aligned}&\left\{q \in \mathscr{T}_{\alpha,d+1} : \theta(\boldsymbol{q}_d^*, q) \leq \left(3\beta\gamma_{d+1}^{1/\tau_{\alpha+1}} C_{b,\alpha+1,1/\tau_{\alpha+1}} M_{d+1,\alpha+1,\boldsymbol{\gamma}}(\tau_{\alpha+1})\right)^{\tau_{\alpha+1}}\right.\\ &\qquad\left.\forall 1 \leq \tau_{\alpha+1} < \alpha+1\right\}\\ &= \mathscr{T}_{\alpha,d+1} \cap \mathscr{F}_{b,\alpha+1}(\beta, \boldsymbol{q}_d^*)\end{aligned}$$

we obtain from the inductive hypothesis and from Lemma 4.3 that

$$\begin{aligned}&\nu\left(\left\{q \in \mathscr{T}_{\alpha,d+1} : \theta(\boldsymbol{q}_d^*, q) \leq \left(3\beta\gamma_{d+1}^{1/\tau_{\alpha+1}} C_{b,\alpha+1,1/\tau_{\alpha+1}} M_{d+1,\alpha+1,\boldsymbol{\gamma}}(\tau_{\alpha+1})\right)^{\tau_{\alpha+1}}\right.\right.\\ &\qquad\left.\left.\forall 1 \leq \tau_{\alpha+1} < \alpha+1\right\}\right) > 1 - \alpha\beta^{-1},\end{aligned}$$

which implies that there are $\lfloor(1-\alpha\beta^{-1})b^{\beta m}\rfloor + 1$ elements to populate $\mathscr{T}_{\alpha+1,d+1}$. Therefore Algorithm 2 finds a $q_{d+1}^* \in G_{b,\beta m}$ such that

$$\theta_\alpha(\boldsymbol{q}_d^*, q_{d+1}^*) \leq \left(3\beta\gamma_{d+1}^{1/\tau_\alpha} C_{b,\alpha,1/\tau_\alpha} M_{d,\alpha,\boldsymbol{\gamma}}(\tau_\alpha)\right)^{\tau_\alpha}$$

for all $1 \le \tau_\alpha < \alpha$ and for all $2 \le \alpha \le \beta$.

Using equation (12) we obtain,

$$\begin{aligned} e_{b^m,\alpha}((\boldsymbol{q}_d^*, q_{d+1}^*), p) &= e_{b^m,\alpha}(\boldsymbol{q}_d^*, p) + \theta_\alpha((\boldsymbol{q}_d^*, q_{d+1}^*)) \\ &\le M_{d,\alpha,\boldsymbol{\gamma}}(\tau_\alpha)^{\tau_\alpha}(1 + (3\beta\gamma_{d+1}^{1/\tau_\alpha} C_{b,\alpha,1/\tau_\alpha})^{\tau_\alpha}) \\ &\le M_{d+1,\alpha,\boldsymbol{\gamma}}(\tau_\alpha)^{\tau_\alpha}, \end{aligned}$$

for all $1 \le \tau_\alpha < \alpha$ and for all $2 \le \alpha \le \beta$. □

5 Optimal convergence rates for a range of smoothness parameters using Korobov polynomial lattice rules

In this section we study a special case of polynomial lattice rules, namely Korobov polynomial lattice rules. We show the existence of higher order Korobov polynomial lattice rules which achieve optimal rates of convergence for a range of smoothness parameters and present an algorithm which shows how to construct such higher order Korobov polynomial lattice rules. This algorithm is the same as the "sieve algorithm" presented in Section 4, but due to the structure of Korobov polynomial lattice rules, the cost of such an algorithm is feasible.

We now present the results which are used to establish the existence of a higher order Korobov polynomial lattice rule achieving optimal rates of convergence for a range of smoothness parameters and its construction. For the remainder of this section, we use $\phi(q) := (q, q^2, \ldots, q^s) \pmod p$, $q \in G_{b,\beta m}$ to denote the generating vector of the higher order Korobov polynomial lattice rule $S_{p,m,\beta m}(\phi(q))$ and $e_{b^m,\alpha}(\phi(q), p)$ to denote the corresponding worst-case error, $2 \le \alpha \le \beta$; we recall that $\alpha \le \beta$ and $n = \beta m$. As in Section 3 we point out that we use generating vectors $\phi(q) := (q, q^2, \ldots, q^s) \pmod p$ instead of $(1, q, \ldots, q^{s-1})$ (see e.g. [5, Algorithm 4.6]), as otherwise the projection onto the first coordinate does not achieve a convergence rate of $b^{-\alpha m}$. We start with the following proposition, which is analogous to Proposition 4.1, where we set

$$\widetilde{A}_{m,n,s,\alpha,p}(\lambda) := \frac{1}{b^n} \sum_{q \in G_{b,n}} e_{b^m,\alpha}^{\lambda}(\phi(q), p)\,.$$

Proposition 5.1 *For $\alpha \geq 2$ and $1/\alpha < \lambda \leq 1$ we have*

$$\widetilde{A}_{m,n,s,\alpha,p}(\lambda) \leq \frac{s+1}{b^{\min(m,\lambda n)}} \left[-1 + \prod_{j=1}^{s} (1 + \gamma_j^{\lambda} C_{b,\alpha,\lambda}) \right].$$

Proof. Using Proposition 2.1 and Jensen's inequality we obtain,

$$\begin{aligned} \widetilde{A}_{m,n,s,\alpha,p}(\lambda) &\leq \frac{1}{b^n} \sum_{q \in G_{b,\beta m}} \sum_{\boldsymbol{k} \in \mathscr{D}_p(\phi(q))} r_{\alpha}^{\lambda}(\boldsymbol{\gamma}, \boldsymbol{k}) \\ &= \sum_{\boldsymbol{k} \in \mathbb{N}_0^s \setminus \{\mathbf{0}\}} r_{\alpha}^{\lambda}(\boldsymbol{\gamma}, \boldsymbol{k}) \frac{1}{b^n} \sum_{\substack{q \in G_{b,\beta m} \\ \overline{\boldsymbol{k}} \cdot \phi(q) \equiv a \pmod p \\ \deg(a) < n-m}} 1. \end{aligned} \tag{13}$$

In the case where all components of $\overline{\boldsymbol{k}}$ are multiples of p every $q \in G_{b,\beta m}$ satisfies the equation $\overline{\boldsymbol{k}} \cdot \phi(q) \equiv 0 \pmod p$ and hence we have

$$\frac{1}{b^n} \sum_{\substack{\boldsymbol{q} \in G_{b,\beta m} \\ \overline{\boldsymbol{k}} \cdot \phi(q) \equiv a \pmod p \\ \deg(a) < n-m}} 1 = 1$$

and the sum over all $\overline{\boldsymbol{k}}$ which satisfy this condition is therefore bounded by

$$\sum_{\substack{\boldsymbol{k} \in \mathbb{N}_0^s \setminus \{\mathbf{0}\} \\ \overline{\boldsymbol{k}} \equiv \mathbf{0} \pmod p}} r_{\alpha}^{\lambda}(\boldsymbol{\gamma}, \boldsymbol{k}) \leq \frac{1}{b^{\lambda n}} \left(-1 + \prod_{j=1}^{s} (1 + \gamma_j^{\lambda} C_{b,\alpha,\lambda}) \right),$$

see the proof of Proposition 4.1.

In the case where there is at least one component of $\overline{\boldsymbol{k}}$ which is not a multiple of p we have

$$\frac{1}{b^n} \sum_{\substack{q \in G_{b,\beta m} \\ \overline{\boldsymbol{k}} \cdot \phi(q) \equiv a \pmod p \\ \deg(a) < n-m}} 1 \leq s b^{-m},$$

because for any choice a there are at most s solutions q to $\overline{\boldsymbol{k}} \cdot \phi(q) \equiv a \pmod p$ and there are b^{n-m} possible choices for a. Therefore this part of equation (13) is bounded by

$$\frac{s}{b^m} \left(-1 + \prod_{j=1}^{s} (1 + \gamma_j^{\lambda} C_{b,\alpha,\lambda}) \right).$$

Altogether we now obtain that

$$\begin{aligned}\widetilde{A}_{m,n,s,\alpha,p}(\lambda) &\leq \left(\frac{s}{b^m}+\frac{1}{b^{\lambda n}}\right)\left(-1+\prod_{j=1}^{s}(1+\gamma_j^{\lambda}C_{b,\alpha,\lambda})\right)\\ &\leq \frac{s+1}{b^{\min(m,\lambda n)}}\left(-1+\prod_{j=1}^{s}(1+\gamma_j^{\lambda}C_{b,\alpha,\lambda})\right)\end{aligned}$$

as required. □

Let ν denote the equiprobable measure on $G_{b,\beta m}$. For $c \geq 1$ and $1 \leq \tau < \alpha \leq \beta$ the following set is introduced:

$$\widetilde{\mathscr{C}}_{b,\alpha}(c,\tau) := \left\{q \in G_{b,\beta m} : e_{b^m,\alpha}(\phi(q),p) \leq \widetilde{E}_{b,\alpha,\boldsymbol{\gamma},s,m}(c,\tau)\right\}, \tag{14}$$

where

$$\widetilde{E}_{b,\alpha,\boldsymbol{\gamma},s,m}(c,\tau) := \frac{c^{\tau}(s+1)^{\tau}}{b^{\tau m}}\left(-1+\prod_{j=1}^{s}(1+\gamma_j^{1/\tau}C_{b,\alpha,1/\tau})\right)^{\tau}.$$

Furthermore, let

$$\begin{aligned}\widetilde{\mathscr{C}}_{b,\alpha}(c) &:= \bigcap_{1\leq\tau<\alpha}\widetilde{\mathscr{C}}_{b,\alpha}(c,\tau) \qquad (15)\\ &= \left\{q \in G_{b,\beta m} : e_{b^m,\alpha}(\phi(q),p) \leq \widetilde{E}_{b,\alpha,\boldsymbol{\gamma},s,m}(c,\tau)\ \forall 1 \leq \tau < \alpha\right\}.\end{aligned}$$

Lemma 5.1 *Let $c \geq 1$ and $1 \leq \tau < \alpha \leq \beta$. Then we have*

$$\nu(\widetilde{\mathscr{C}}_{b,\alpha}(c,\tau)) > 1 - c^{-1}.$$

Proof. The proof follows exactly along the lines of the proof of Lemma 4.1. □

Lemma 5.2 *Let $c \geq 1$. Then we have*

$$\nu(\widetilde{\mathscr{C}}_{b,\alpha}(c)) > 1 - c^{-1}.$$

Proof. The proof follows exactly along the lines of the proof of Lemma 4.2. □

Algorithm 3 Korobov sieve algorithm

Require: b a prime, $s, m, \beta \in \mathbb{N}$, $\beta \geq 2$, and $p \in \mathbb{Z}_b[x]$ with $\deg(p) = \beta m$.

1: Set $\mathscr{T}_1 := G_{b,\beta m}$.
2: **for** $\alpha = 2$ to β **do**
3: perform a computer search to find $\lfloor (1-(\alpha-1)\beta^{-1})b^{\beta m} \rfloor + 1$ elements q in $\mathscr{T}_{\alpha-1}$ to populate the set $\mathscr{T}_\alpha$, which is a subset of

$$\left\{ q \in \mathscr{T}_{\alpha-1} : e_{b^m,\alpha}(\phi(q), p) \leq \widetilde{E}_{b,\alpha,\boldsymbol{\gamma},s,m}(\beta, \tau_\alpha) \, \forall 1 \leq \tau_\alpha < \alpha \right\}$$

4: **end for**
5: Select $q^* \in \mathscr{T}_\beta$
6: **return** q^*.

As in Section 4 we now introduce a "sieve algorithm" (see Algorithm 3) which shows how to obtain a generating vector for a higher order Korobov polynomial lattice rule, which achieves optimal convergence rates for a range of smoothness parameters. The next theorem shows that Algorithm 3 does indeed produce such a vector.

Theorem 5.1 *Let $s, m, \beta \in \mathbb{N}$, $\beta \geq 2$. Then Algorithm 3 finds an element $q \in G_{b,\beta m}$ such that*

$$e_{b^m,\alpha}(\phi(q), p) \leq \frac{(s+1)^{\tau_\alpha} \beta^{\tau_\alpha}}{b^{\tau_\alpha m}} \left(-1 + \prod_{j=1}^{s} (1 + \gamma_j^{1/\tau_\alpha} C_{b,\alpha,1/\tau_\alpha}) \right)^{\tau_\alpha},$$

for all $1 \leq \tau_\alpha < \alpha$, $2 \leq \alpha \leq \beta$.

Proof. We prove the result by induction on α. For $\alpha = 2$, by Lemma 5.2,

$$\nu\left(\widetilde{\mathscr{C}}_{b,\alpha}(\beta) \right) > 1 - \beta^{-1}, \forall 2 \leq \alpha \leq \beta,$$

so there are at least $\lfloor (1-\beta^{-1})b^{\beta m} \rfloor + 1$ vectors to populate the set $\mathscr{T}_2$. We now assume that there are $\lfloor (1-(\alpha-1)\beta^{-1})b^{\beta m} \rfloor + 1$ elements in the set $\mathscr{T}_\alpha$, where $2 \leq \alpha < \beta$, hence $\nu(\mathscr{T}_\alpha) > 1 - (\alpha-1)\beta^{-1}$. We want to show that

$$\nu\left(\left\{ q \in \mathscr{T}_\alpha : e_{b^m,\alpha+1}(\phi(q), p) \leq \widetilde{E}_{b,\alpha+1,\boldsymbol{\gamma},s,m}(\beta, \tau_{\alpha+1}) \, \forall 1 \leq \tau_{\alpha+1} < \alpha+1 \right\} \right) > 1 - \alpha\beta^{-1}, \tag{16}$$

which implies that there are $\lfloor (1-\alpha\beta^{-1})b^{\beta m} \rfloor + 1$ elements to populate the set $\mathscr{T}_{\alpha+1}$. Since

$$\begin{aligned}&\left\{ q \in \mathscr{T}_\alpha : e_{b^m,\alpha+1}(\phi(q),p) \le \widetilde{E}_{b,\alpha+1,\boldsymbol{\gamma},s,m}(\beta,\tau_{\alpha+1}) \,\forall 1 \le \tau_{\alpha+1} < \alpha+1 \right\} \\ &= \mathscr{T}_\alpha \cap \widetilde{\mathscr{C}}_{b,\alpha+1}(\beta)\end{aligned}$$

we obtain equation (16) from the induction assumption and from Lemma 5.2. □
